Abstract

1 Introduction

The use of machine learning for problem solving has risen in popularity as large data sets have become available for analysis. There now exists many different methods in varying complexity for both supervised and unsupervised learning. All of these methods have advantages and drawbacks, as well as many similarities. This means we can get familiar with some of the central themes in machine learning by studying simple algorithms. In this report, we will implement three different supervised learning algorithms with increasing complexity, as well as the k-fold resampling technique.

2 Theory

2.1 Ordinary least squares

2.2 Ridge regression

2.3 Lasso regression

2.4 Mean squared error

2.5 Score function

2.6 k-fold cross validation

There are several ways of estimating the skill of a machine learning model. One such procedure is the k-fold cross-validation, which is used when working with a limited data sample.

Shuffle the dataset randomly;
Divide the dataset into k folds;
foreach k **do**
    Take the kth fold out to use as test data set;
    Set the remaining folds as training data set;
    Fit a model to the training set;
    Evaluate the model on the test set;
    Retain the evaluation score and discard the model ;
Calculate the mean of the evaluation scores;

Algorithm 1: The k-fold cross-validation algorithm.

$$
A = \begin{bmatrix}
b_1 & c_1 & 0 & \dots & \dots & 0 \\
a_1 & b_2 & c_2 & 0 & \dots & 0 \\
0 & a_2 & b_3 & c_3 & \dots & 0 \\
\vdots & \ddots & \ddots & \ddots & \ddots & \vdots \\
0 & \dots & \ddots & a_{n-2} & b_{n-1} & c_{n-1} \\
0 & \dots & \dots & 0 & a_{n-1} & b_n
\end{bmatrix},
$$
